

Rage Against the Machines and the Democratic Hourglass?

Examining Outcomes in Counterinsurgency Wars

The Puzzle

In counterinsurgency wars, what explains the decreasing likelihood of counterinsurgent (incumbent) victory, as seen in figure 1?

Figure 1

Lyall and Wilson (2009) hypothesize that this is a function of the increasing mechanization of incumbent military forces, as seen in figure 2.

Authors' Results

Using an ordinal DV representing the incumbent's war outcome (*win, lose, draw*), the three logit models above represent the authors' central findings. Substantively, they find that: (1) the modern (post WWI) era, increasing mechanization, and the use of helicopters are all associated with lower probability of incumbent victory; (2) *support* and *occupy* are also associated with incumbent defeat; and (3) *regime* is not a significant predictor of the incumbent's outcome.

Figure 3. The conditional effect of mechanization. Predicted values computed using model 6, with a cubic spline curve fitted across median values. $N=167$.

Cross Validation of the Models

The figures above display the results of cross-validations for all three models. The similarity of the densities indicates that there does not appear to be any data unduly influencing the model estimations.

Statistical Simulations

- The dichotomous variables *modern* and *heli* are associated with a higher probability of incumbent loss.
- Incorporating the fundamental uncertainty indicates that *mech* is not as strong a predictor of outcome.
- *Occupy* and *support* are strong negative predictors of incumbent victory.
- There is no significant difference in probability of victory for democracies and non-democracies.

Re-specification

As an extension of the authors' analysis, I wish to test the interaction of conflict *duration* with *democ* by re-specifying model 6. The results of this re-specification are illustrated in model 6.1. A simple likelihood ratio test between model 6 and 6.1 results in a $p \leq 0.05$, thus indicating a better fit of the re-specified model.

Regime Type and Duration

This plot represents the marginal effect of duration on probability of incumbent victory for democracies and non-democracies. The solid lines represent the point estimates, and the shaded areas represent the 95% confidence bands.

High uncertainty makes it difficult to draw definitive conclusions, but we can identify the following:

- Probability of victory for democracies trends negatively as *duration* increases.
- Probability of victory for non-democracies is relatively constant as *duration* increases.
- High uncertainty in shorter conflicts gives rise to less uncertainty as *duration* increases.
- Further empirical analysis is needed in order to gain a robust understanding of the relationship between *duration* and regime type.
